## Cartilage

## Tendon

### STAGE OF KNEE OSTEOARTHRITIS

## BASIC PRINCIPLE AND CORE SET

Combination of treatment modalities, including non-pharmacological and pharmacological therapies is strongly recommended

**Core set:** - Information/Education

- Weight loss if overweight
- Exercise program (aerobic, strengthening)

## STEP 1: Background treatment

if symptomatic

- (Paracetamol on a regular basis)  
OR
- Chronic SYSADOA: prescription glucosamine sulfate and/or chondroitin sulfate ± as needed paracetamol

if still symptomatic ADD

- Topical NSAIDs  
(OR)
- (Topical capsaicin)

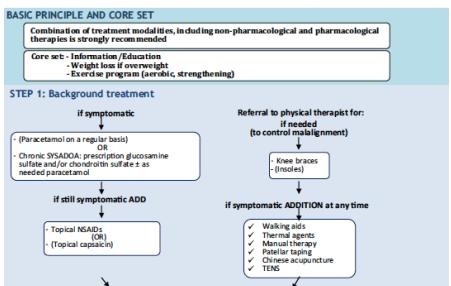

Referral to physical therapist for:

if needed  
(to control malalignment)

- Knee braces
- (Insoles)

if symptomatic ADDITION at any time

- ✓ Walking aids
- ✓ Thermal agents
- ✓ Manual therapy
- ✓ Patellar taping
- ✓ Chinese acupuncture
- ✓ TENS

## STEP 2: Advanced pharmacological management in the persistent symptomatic patient

if still or severely symptomatic

- Intermittent or continuous (longer cycles) oral NSAIDs

### NORMAL GI RISK

- Non-selective NSAID with PPI
- Cox-2 selective NSAID (consider PPI)

### INCREASED GI RISK\*

- Cox-2 selective NSAID with PPI
- Avoid non-selective NSAIDs

### INCREASED CV RISK

- Prefer naproxen
- Avoid high-dose diclofenac and ibuprofen (if on low-dose aspirin)
- Caution with other non-selective NSAIDs
- Avoid Cox-2 selective NSAIDs

### INCREASED RENAL RISK

- Avoid NSAIDs†

\*Including use of low dose aspirin

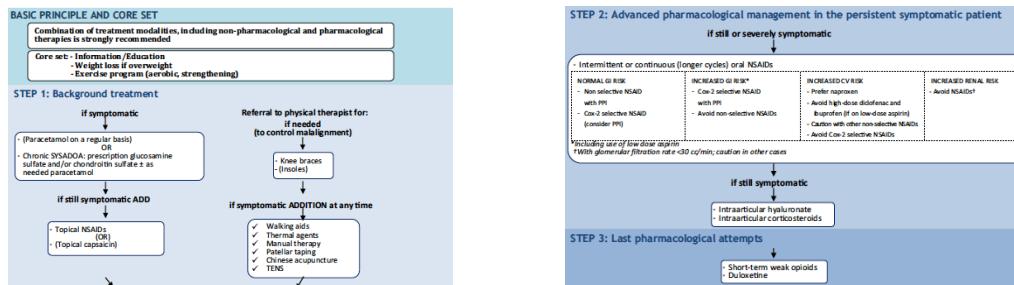

†With glomerular filtration rate <30 cc/min; caution in other cases

if still symptomatic

- Intraarticular hyaluronate
- Intraarticular corticosteroids

## STEP 3: Last pharmacological attempts

- Short-term weak opioids
- Duloxetine

## STEP 4: End-stage disease management and surgery

if severely symptomatic and poor quality of life

- Total joint replacement
- (Unicompartimental knee replacement)

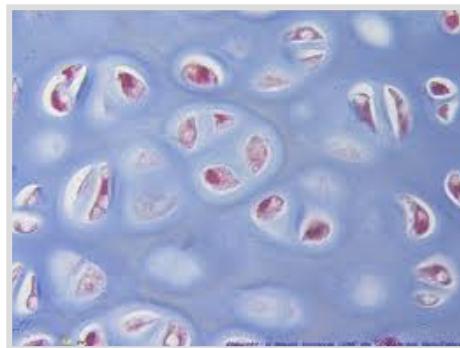

if contraindicated

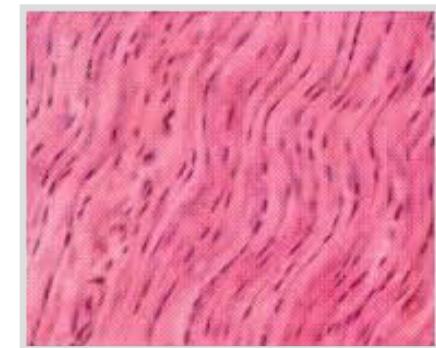

- Opioid analgesics

# Tendinopathies

## Strong evidence against platelet-rich plasma injections for chronic lateral epicondylar tendinopathy: a systematic review

Robert-Jan de Vos,<sup>1,2,3</sup> Johann Windt,<sup>4</sup> Adam Weir<sup>1</sup>

**British Journal of  
Sports Medicine**

**Background** Chronic lateral epicondylar tendinopathy is frequent in athletes, and platelet-rich plasma (PRP) is being used increasingly in its treatment.

**Objective** To systematically review the literature on the efficacy of PRP injections for chronic lateral epicondylar tendinopathy.

**Methods** The databases of PubMed, EMBASE, CINAHL, Medline OvidSP, Scopus, Google Scholar, Web of Science and Cochrane Library were searched in October 2013. Inclusion criteria were a clinical diagnosis of chronic lateral epicondylar tendinopathy, a randomised controlled trial, an intervention with a PRP injection and the outcome measures described in terms of pain and/or function. One author screened the search results and two authors independently assessed the study quality using the Physiotherapy Evidence Database (PEDro) score. A study was considered to be of high quality if its PEDro score was  $\geq 6$ . A best evidence synthesis was used to identify the level of evidence.

**Results** 6 studies were included, of which four were considered to be of high quality. Three high-quality studies (75%) and two low-quality studies showed no significant benefit at the final follow-up measurement or predefined primary outcome score when compared with a control group. One high-quality study (25%) showed a beneficial effect of a PRP injection when compared with a corticosteroid injection (corticosteroid injections are harmful in tendinopathy). Based on the best evidence synthesis, there is strong evidence that PRP injections are not efficacious in chronic lateral epicondylar tendinopathy.

**Conclusions** There is strong evidence that PRP injections are not efficacious in the management of chronic lateral elbow tendinopathy.
